The ICL

The ICL

The beginning

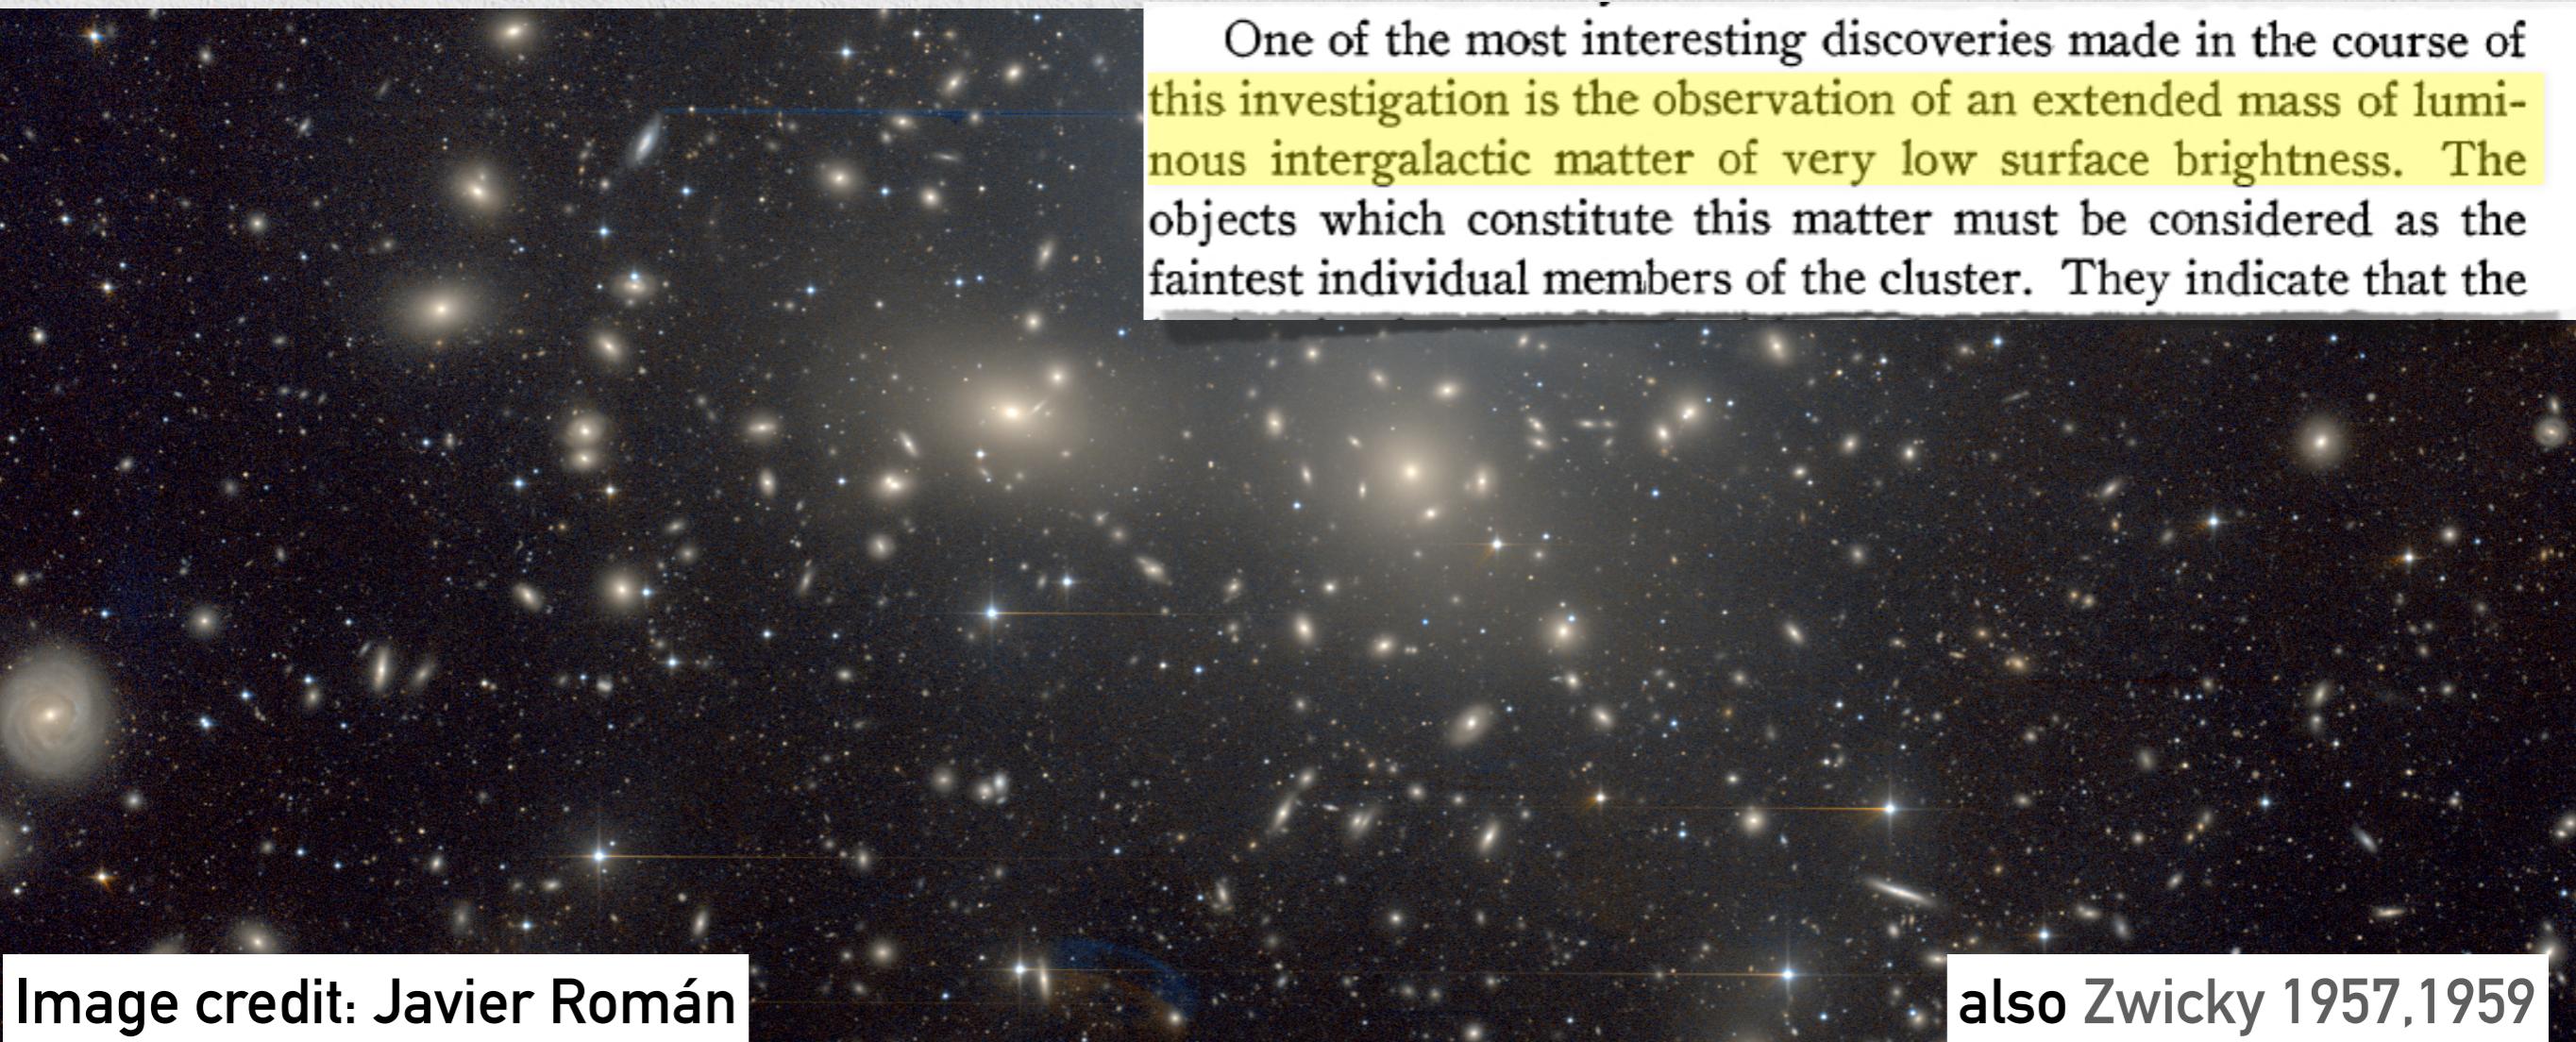

Diffuse light proposed by Zwicky 1937

field nebulae. In the second place, we should expect a considerable number of stars, as well as matter in dispersed form from disrupted nebulae, to be scattered through the internebular spaces within clusters. Sufficiently large amounts of internebular matter in clusters

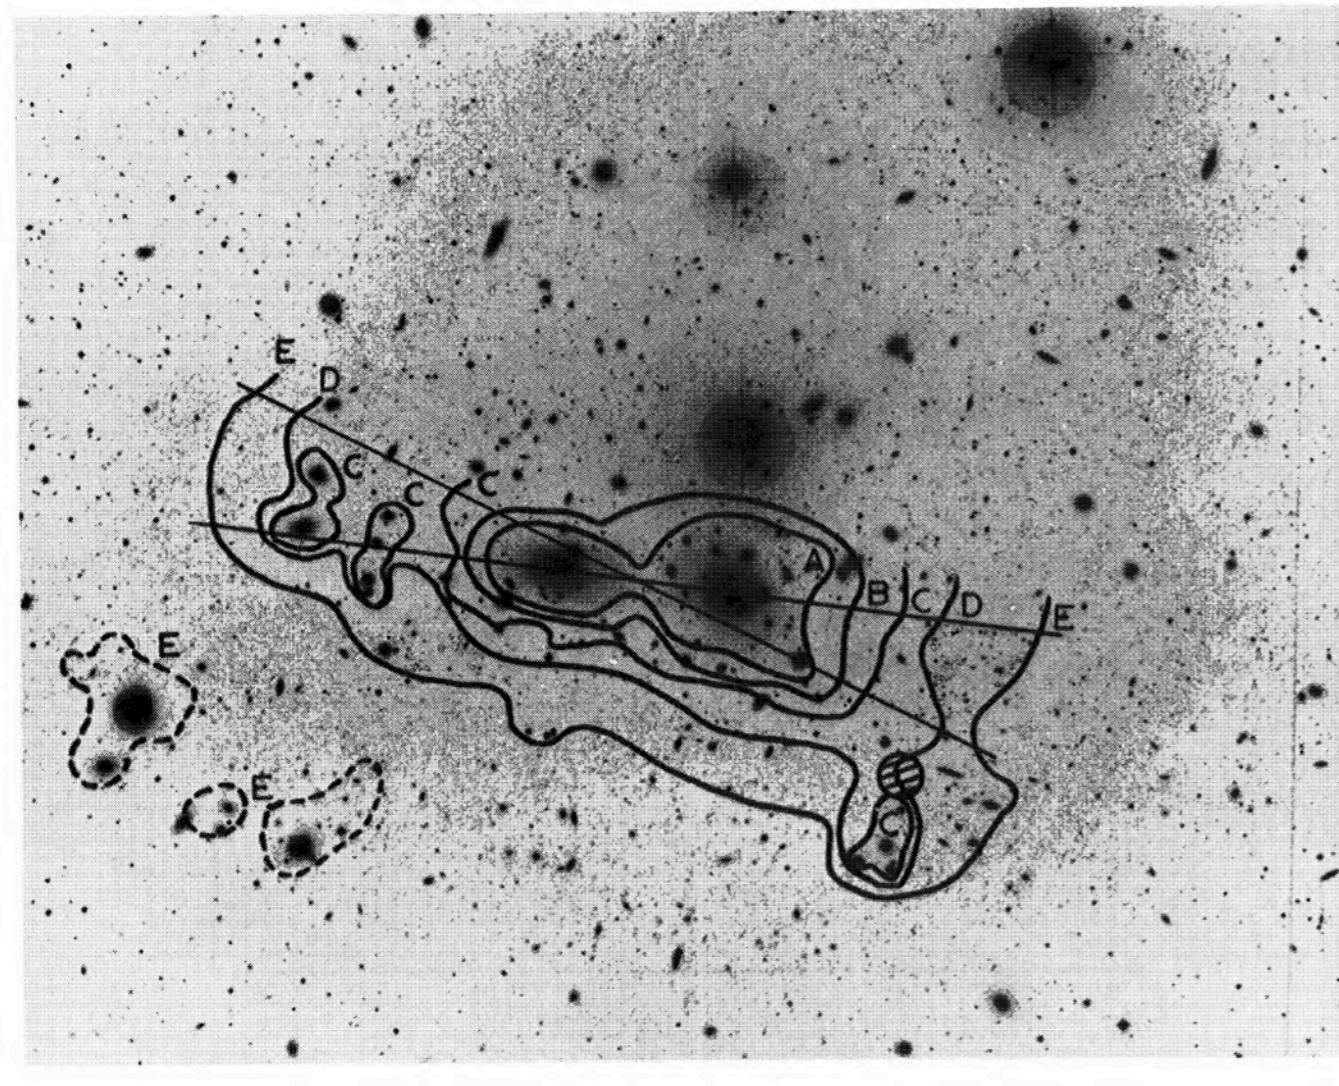

and first observed by Zwicky 1951 in Coma

One of the most interesting discoveries made in the course of this investigation is the observation of an extended mass of luminous intergalactic matter of very low surface brightness. The objects which constitute this matter must be considered as the faintest individual members of the cluster. They indicate that the

Conclusions

- ICL is **ubiquitous** in clusters of galaxies. Formed by stars following the potential of the cluster.
- The ICL encodes the history of hierarchical assembly of the cluster. And makes simulations agree with the observed BCG mass evolution.
- Luminous tracer of dark matter.
- It forms via tidal stripping of massive satellites.

Conclusions
